Foreward

NEPROPLAST (New Products Industries) was established in 1969 as a first manufacturing facility to introduce uPVC piping systems in Saudi Arabian market. Since its establishment, NEPROPLAST has followed a strict policy in producing high quality pipes. Using state-of-the-art equipments and tools in its production facilities, hiring highly trained professionals and working with experienced team of industry consultants. The initial production of NEPROPLAST uPVC pipes were manufactured according to British Standards specifications BS 3505/3506. At a later stage, NEPROPLAST actively participated with Saudi Arabia Standard Organization SASO to set the Saudi Arabian Standard SAS 14/15/1396. In the mid 80's NEPROPLAST started the production of PVC pipes and fittings according to ASTM Standards for Schedule 40, Schedule 80 and CPVC pipes for Schedule 80.

By producing a wide range of pipes and fittings according to different standards, NEPROPLAST has established for itself a strong position in the market to serve the construction industry in the fields of water network pressure lines, sewerage and drainage non-pressure lines and electrical & telecommunication conduits. NEPROPLAST made its pipes and fittings available in both options to Rubber Ring or Solvent Cement jointing systems.

In 2009, NEPROPLAST made a significant move into modern, heavy metal free stabilizers for all its uPVC & cPVC products. A move which ensured total elimination of toxicological content in its entire product range. Organic stabilizers pipes and fittings ensure a safe drinking water supply, free of any possible toxic traces which can develop through the use of heavy metal uPVC stabilizers.

All NEPROPLAST drinking water products are now accredited through NSF, proof of its excellent health safety factor. NEPROPLAST added to its products portfolio range covers pipes and ducts to serve the water, gas electrical and telecommunication applications. NEPROPLAST recently introduced to the market the Polyethylene Corrugated-Optic-Ducts (COD) as a unique product for fiber optic and electrical cabling installations.

All NEPROPLAST products are marketed and sold through National Marketing Est. Co. Ltd. which has more than 23 branches covering all cities and urban areas across the Kingdom of Saudi Arabia. National Marketing Est. Co. Ltd. has an export department responsible for exporting NEPROPLAST products to Middle East and North African (MENA) markets. In addition to NEPROPLAST products, National Marketing Est. Co. Ltd. imports a wide range of fittings, valves, solvent cements and other accessory components. Now-a-days, National Marketing Est. Co. Ltd. is considered the largest trading company in Saudi Arabia that has all kinds of plastic, pipes, fittings, valves and cements available in its stocks for all traders and contractors in the Saudi market.

Both NEPROPLAST and National Marketing Est. Co. Ltd. strive to be the largest quality leaders in the supply of plastic piping systems to serve the sectors of water, gas, electrical & telecommunication across Middle East.

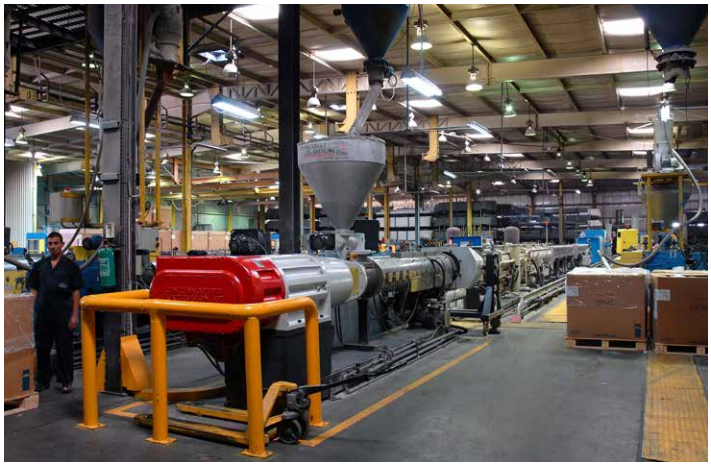
Index



I. Manufacturing Standards

NEPROPLAST uPVC pipes are manufactured in accordance with

- Saudi Arabian standards SASO ISO – 1452 – 2 has superseded SSA 14 and 15, which size and dimensions appears on the next page.
- ISO (International Organization for Standardization) 161/1 which conforms to German Standard DIN 8061, 8062 and 19532 & 19534.
- Saudi Arabian Standards (SSA 255, 254 / (1981) Conforming to BS EN 50086 - 1:1994 for Electrical Conduits replaces BS 6099:Part1:1981.
- British Standards, BS 3505, BS 4660, BS 5481.
- ASTM Standards ASTM D-1785, for (Sch. 40, 80) ASTM D-2241 (SDR), ASTM D-2665, ASTM F-441, F-439.
- NEMA Standards TC-2, TC-6 and TC-8, TC-3/TC-9.
- EN Standard Pr EN 1401, Pr EN 1452-2.
- DIN 4925 and SASO 1783 / 1784 for Well Casing & Screen.

Range of Production

- Pipes from NEPROPLAST are manufactured according to SSA and DIN Standards from 16mm up to 710mm outside diameter in various pressure & classes, details of which are shown in this catalogue on Page no. 6 Table - 1.
- SSA uPVC pipes are available with spigot and solvent weld socket joints for diameter less than 63mm. Sizes of outside diameter 63mm and larger are available with both mechanical rubber ring joints or solvent weld socket joints.
- Pipes manufactured in accordance with BS & ASTM Standards range from 1/2 inch up to 8 inches in various pressure ratings.
- BS & ASTM PVC pipes are available with plain spigot and socket joints only.
- NEPROPLAST pipes are produced in 6 meters standard length (other lengths are available on request), standard colors are grey, white and black (other colors are available on request). Such as orange, brown, black & blue.

Product Development

NEPROPLAST is adopting a policy of continuous development and research as an integral part of its operation. Consistently expanding its range of PVC & cPVC fittings. For further details, please contact our Technical Sales Dept.

Marking

NEPROPLAST uPVC pipes are marked automatically during the process of production. Each pipe is marked according to its relevant standard classifications. Special marking can be added on request.

315	545	403	185	478	204
355	588	434	194	520	224
400	612	485	205	570	246

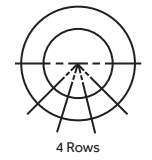
Dimensions stated above are indicative, detailed specification for design purposes should be obtained from our Technical Sales Department. (L= Length)

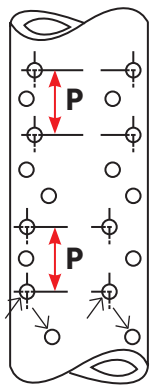
V. Perforated and Slotted uPVC Pipes

NEPROPLAST perforated or slotted uPVC pipes are manufactured upon request depending on the size and class of the pipes. Below given figures is a general configuration which may vary as per clients requirements.

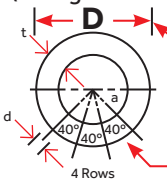
A) PERFORATED PIPE

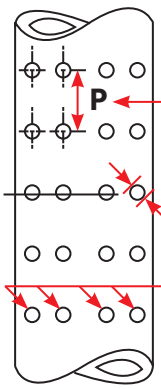
(Staggered Rows)





(Straight Rows)

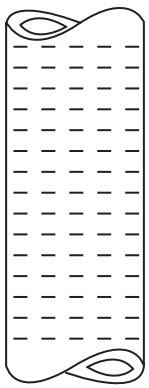




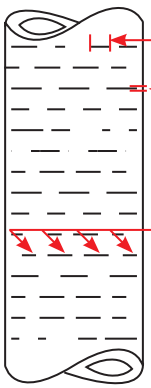
Range of sizes	75 mm to 500 mm
Angular pitch of holes	40° for 3 or 4 rows 40°, 80° or 120° for 2 rows
Longitudinal pitch of holes (LP)	50 mm to 200 mm
Hole Diameter	6 mm to 13 mm
Number of rows	1 to 6

B) SLOTTED PIPE

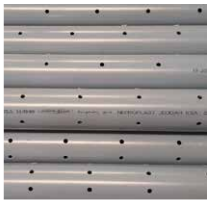
(Straight Slots)



(Staggered Slots)



Slot length	Depends on the size
Slot width	1, 1 1/2, 2 & 3 mm
No. of Rows	4, 6 & 8 (but according to the size)
Slot Angle (Sector)	Recommended by **NEPROPLAST**



For further details please refer to National Marketing Technical Sales Department

Table No. 18.0 **Properties of NEPROPLAST uPVC Pipes**

Properties		
MECHANICAL	**Unit**	**Values**
Tensile Strength Ultimate	kgf/cm² MPA	492.5 min 48.3 min
Modulus of Elasticity in Tension	kgf/cm² MPa	28123 min 2758 min
Compressive Strength	kgf/cm² MPa	632.2 min 62.0 min
Flexural Strength	kgf/cm² MPa	1020 100.0 min
Izod Impact Strength	j/m of notch	34.7 min
Hardness	Durometer "D" Rockwell "R"	>70±3 110-120
THERMAL PROPERTIES	**Unit**	**Values**
Coefficient of Thermal Linear Expression		5.6
Thermal Conductivity	Wm/ °k /m²	0.18
Specific Heat	cal / °C kcal /kg °C	0.23 0.23
Vicat Softening Temperature	°C	> 80
Deflection Temperature	°C	> 70 min
Elongation at Break	%	> 40 min
ELECTRICAL PROPERTIES	**Unit**	**Values**
Dielectric Strength	Volts / Mil	1100
Dielectric Constant	60 cps @ 30°C	4
Specific Volume Restivity	Ohm / cm	> 10^{14}
Power Factor	at 10 cycles	3
GENERAL PROPERTIES	**Unit**	**Values**
Specific Gravity		1.42 min
Water Absorption	mg/cm²	< 4
Cell Designation	ASTM 1784	12454
Flame Spread E-84		< 25
Poison's Ratio @ 73°F		0.35 - 0.38
Friction Coefficient	Factor "C"	150

uPVC is a non-conductor of electricity and also not subject to galvanic or electrolytic attack. Electrical equipments should not be earthened to (uPVC) pipes.

VI. Chemical Resistance of NEPROPLAST uPVC Pipes

NEPROPLAST uPVC & cPVC pipes and fittings have excellent chemical resistance to most mineral acids, bases, salts and aliphatic hydrocarbons. When they used within their allowable pressure and temperature ranges they will provide a good alternative to metallic piping which corrodes when exposed to the same aggressive chemical solutions. The informatin contained in the following chemical resistance tables are based on data supplied to us by our raw material manufacturers and some actual field experience gathered from various sources. You must take into consideration the specific use conditions that will apply to your project. There will be variables that will affect the chemical resistance such as temperature, pressure, chemical concentration and external stresses that may exist in the design and construction of the system. Because of the wide variety and numeroud use conditions that are found in the process of chemical industry, the final decision is to use thermoplastic piping should be based on in-service testing and evaluation by the responsible engineer and end-user.

INTERPRETATION OF THE DATA

It is important to understand that an "R" rating does not necessarily imply that pipe, fittings and joint can be used at their water pressure rating and be expected to have the same longevity when used with a particular chemical other than water. Generally, the chemical resistance of uPVC will decrease with an increase in temperature and concentrations. This is also true for all other components in the system that will come in contact with the flow. Solvent cements, valves, instrumentation, O-rings, gaskets and other such components should be evaluated and approved by their respective manufacturers.

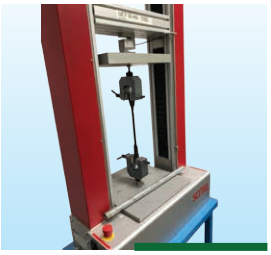
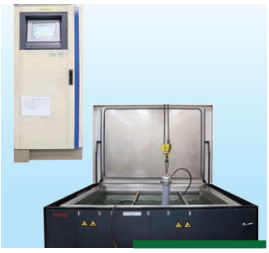
VII. Quality Control Equipment



TENSILE STRENGTH
Measures the strength of material (Resistance) being pulled apart.

MODULUS OF ELASTICITY
Measures the stiffness of the material

ELONGATION AT BREAK
Measures the extension length of the sample until it breaks.



HYDROSTATIC STRENGTH
Determines the capability of the sample to withstand internal pressure for both long and short periods of time.

LONGITUDINAL REVERSION OR EFFECTS OF HEATING
Measures change in length of the sample after exposure to high temperature and the ability to resist heat without showing delamination, cracks or blisters.

BRABENDER
Used for quality control testing and evaluation of raw materials for optimization of production process.

EXTRUSION QUALITY / METHYLENE CHLORIDE / ACETONE
Determines if the plastification of the material is adequate.

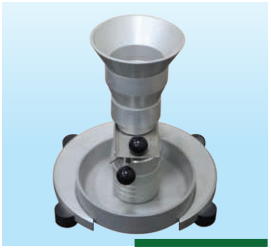
FLATTENING / STIFFNESS
Measures the ability of sample to resist deformation under load. This test is particularly useful for buried installation of pipes.

VICAT SOFTENING TEMPERATURE
Determines the softening temperature of material when penetrated by a flattened needle to 1.0 mm depth under a specific load.

IMPACT STRENGTH
Measures the toughness of the sample against impact or the ability of the sample to absorb applied energy.

DENSITY / SPECIFIC GRAVITY
Determines the specific gravity and density to help in material identification.

FLOW TIME
Measures the pourability of powder materials and useful indication of the ability of the material to pass through hoppers to deliver uniform weight.



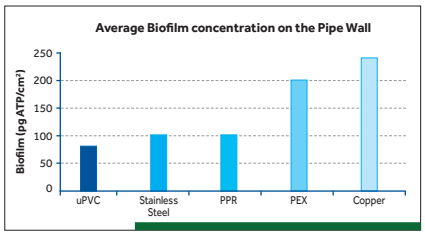
BULK DENSITY
Measures the degree of compactness of a given volume of the material, indicating processing properties.

VIII. General Advantages of NEPROPLAST uPVC Pipes

8.1 Corrosion Resistance & Scale Build up

NEPROPLAST uPVC pipes are chemically resistant to nearly all acids, alkalis, alcohols, halogens as well as many other corrosive fluids. Being non-conductor of electricity, it eliminates galvanic or electrolytic corrosion which is the cause of expensive repairs. NEPROPLAST uPVC non-corroding properties ensure improved flow, lower maintenance costs and longer performance life.

8.2 Low Bacteria Build up

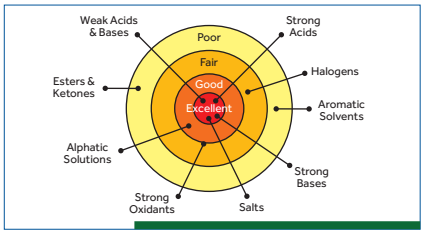


Studies shows that bacteria build up with NEPROPLAST uPVC pipes are far lower than with alternative piping materials. NEPROPLAST uPVC piping systems are resistant to fungi and bacteria growth, particularly those which cause corrosion in metal piping systems.

8.3 Reduced Additive Migration

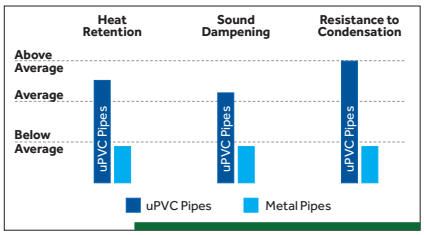
NEPROPLAST uPVC pipes do not allow migration of additives into water supply and hence no bad odour or taste of drinking water.

8.4 Chemical Resistance



NEPROPLAST uPVC pipes inhibit excellent chemical resistance against most acids, alcohols, alkalis, salt solutions and halogens. For specific applications see the NEPROPLAST chemical resistance guide.

8.5 Thermal Conductivity

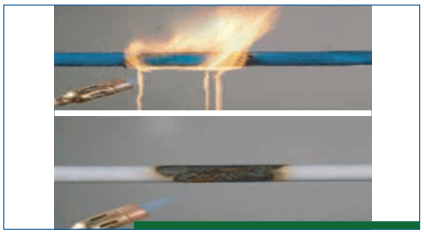


NEPROPLAST uPVC pipes have lower thermal conductivity than for metal which reduces heat losses and offer better uniform fluid temperature, prevent "sweating" formation of condensation on the pipe wall. Insulation in certain instances, may be completely eliminated.

8.6 Mechanical Strength

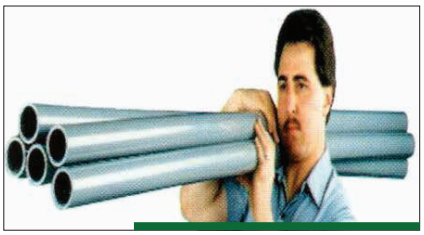
NEPROPLAST uPVC pipes are light in weight having a specific weight which is about one fifth of steel pipes. This will cut down on transportation costs and facilitate pipes installation.

8.7 Fire Proof



NEPROPLAST uPVC pipes do not support combustion and are self extinguishing. Pipes will not burn unless an external flame source is applied.

8.8 Ease of Handling, Installation & Maintenance



NEPROPLAST uPVC pipes are quick and easy to install and maintained with complete range of solvent cement fittings saving time, effort and money as it is light in weight and easy to handle.

8.9 Fluid Friction

NEPROPLAST uPVC pipes being a mirror-smooth inner surface has lower friction loss as compared to metals, i.e. lower pressure losses.

IX. Application of NEPROPLAST uPVC pipes

9.1 Water Supplies

Non-toxic NEPROPLAST uPVC pipes will not affect the taste, color or smell of drinking water. They will never corrode and are therefore extremely sanitary. Deposits and scales will not build up inside as in the case for conventional steel pipes. Their strength is greater than that of asbestos pipes. NEPROPLAST obtained SASO certification and NSF 61 for drinking water use.

9.2 Irrigation Systems

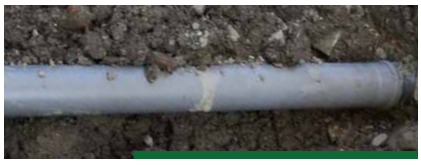
NEPROPLAST uPVC pipes are ideal for agricultural irrigation and sprinkler systems. Non-corrosive NEPROPLAST uPVC pipes are perfect for carrying water which contains chemical fertilizers and insect inhibitors. Within a thick wall and large diameter NEPROPLAST uPVC pipes liquids can be transported under high pressure, which is convenient for the management of large volumes.

9.3 NEPROPLAST uPVC Pipes Casing & Screen

Engineering difficulties and the probability of adverse chemical reactions, make it impractical to overcome corrosion and encrustation through the use of protective coating, chemical treatment or cathodic protection. Thus, NEPROPLAST non-corrosion PVC pipes for water well casing and screen rapidly received approval by the appropriate ministry consultants and engineers.

9.4 Industry

Resistant to most chemicals, NEPROPLAST uPVC pipes have an important role to play in industrial plants. Light, non-corrosive and easy to assemble they allow more complex piping work than with steel or cast-iron pipes.

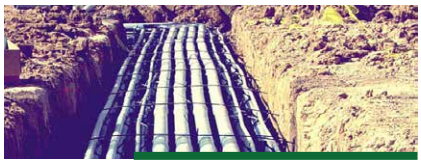


9.5 Soil, Waste & Drainage Sewer System

Waste lines for corrosive gases, ventilation for office buildings and factories, drainage systems for private homes and elevated highways these are a few of the many possibilities for NEPROPLAST uPVC pipes. A full line of uPVC fittings is available to ensure easy installation.

9.6 Mining

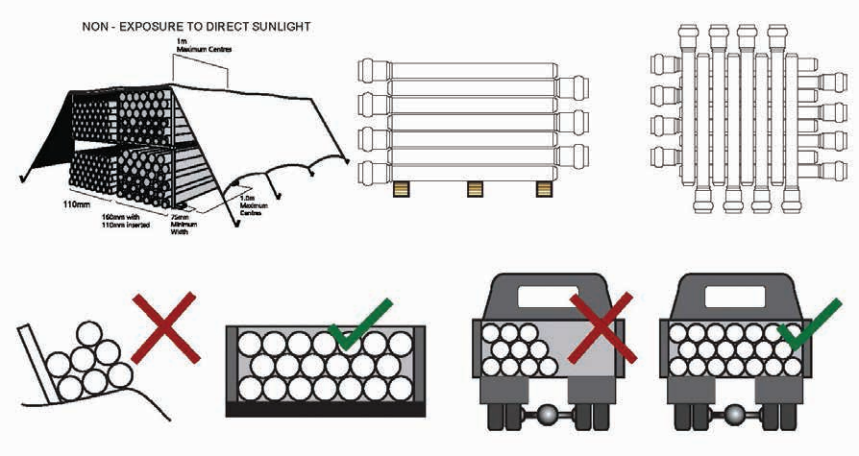
NEPROPLAST uPVC pipes particularly are well suited for draining corrosive liquids found in mines. They make an ideal vent line for pits because they are easily installed in hard to reach places.



9.7 Electrical & Telecommunication Cables Protection

NEPROPLAST uPVC pipes form an integral insulator, hence there is an ever increasing demand for them as electrical conduit. To facilitate work, a full line of fittings is available and fabricated from the same material as the pipes.

X. Transport, Handling & Storage



Unplasticized PVC pipes are strong but light, its specific gravity being approximately one-fifth of cast iron. As a result, these pipes are more easily handled than their metal counterparts. Reasonable care, however, should be exercised at all times and when off loading pipes should be lowered not dropped to the ground.

Pipe should be given adequate support at all times. Pipes should not be stacked in large piles especially in warm temperature conditions as the lower layers may distort, resulting in difficulties when joining and for pipe alignment. Any pipe with ends prepared for joining (socket and spigot joints, RR joints, etc.) should be stacked in layers with the socket, placed at alternate ends of the stack and with sockets protruding to avoid lop-sided stacks and the imparting of permanent set of pipes. Particularly in the case of ring pipe, rubber rings should not be exposed to solar radiation for any length of time if they ar not coated. It is recommended to stock them in a cool and shady place. Rubber rings should not come in touch with chemicals, grease, oil and should not be stored for too long time.

For long-term storage, pipe racks should provide continuous support, but if this is not possible, timber of at least 75 mm bearing width at spacing not greater than 1m centers for pipe sizes 150 mm and above, should be placed beneath the pipes and at 2 m centers at the side, if the stacks are rectangular. These spacing apply to pipe size 160 mm and above. Closer supports will be required for sizes below 160 mm. In such pipe racks, pipes may be stored not more than seven layers or 1.5 m high, whichever is the lesser, but if different classes of pipe are kept in the same racks, then the thickest classes must always be at the bottom.

For temporary storage in the field, where racks are not provided, the ground should be level and free from coarse stones. Pipes stored thus should not exceed three layers high and should be staked to prevent movement.

Stack heights should be reduced if pipes are nested, i.e. pipes stored inside pipes of larger diameters. Reductions in height should be proportional to the weight of the nested pipe compared to the weight of the pipes normally contained in such stowage's.

Since the soundness of any joint depend on the condition of the spigot and the socket, special care must be taken in transit, handling and storage to avoid damage to the ends.

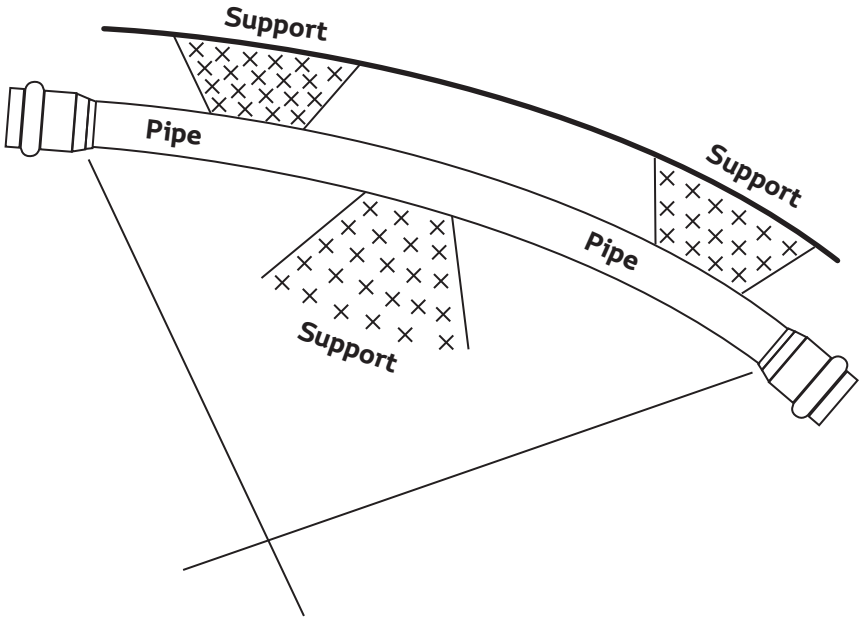
When loading pipes on the vehicles, care must be taken to avoid their coming into contact with any sharp corners such as cope irons, loose nail-heads, etc., as pipes may be damaged by being rubbed against these during transit whilst in transit pipes shall be well secured over their entire length and not allowed to project unsecured over the tailboard of the lorry. Pipes may be off loaded from lorries and or by rolling them gently down timbers, care being taken to ensure that pipes do not fail one upon another nor on any hard or uneven surfaces. Fork-lift trucks will have to be used for bundles and large unit loads.

DEFLECTION

The ring integral socket permits an angular deflection at the joint of approx. 1.0 degree. The introduction of joint deflection is however, generally unnecessary flexible uPVC pipeline. Sufficient flexibility is provided by individual pipe lengths to enable gentle curves to be negotiated without imparting deflection at the joints.

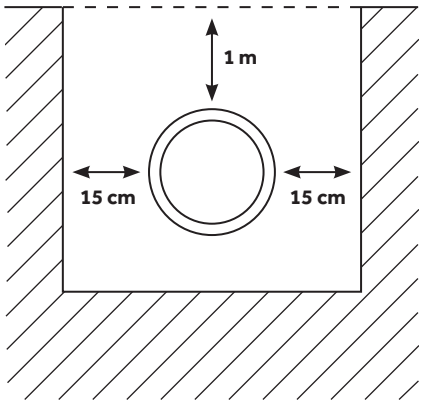
As general guide the cold bending radius R of a uPVC pipe length can be calculated as follows;

R=300 X External Diameter (where a shorter radius of curvature is required, then uPVC formed bends must be introduced).



XI. Installation

UNDERGROUND INSTALLATION TRENCH WIDTH PREPARATION COVER AND BACKFILLING



The width of trench for most purposes is enough to be 30 cm wider than the diameter of the pipe to allow enough room for jointing. Depth of cover should be at least 1 m from top of pipe to ground surface (it is wise to consider in early planning stages how future road widening plans could affect this depth of cover and to consider the frosting depth according to the local climate).

When laying NEPROPLAST water mains piping the usual recommendations relating to sound pipe laying practice should be followed. However, in view of the greater flexibility of uPVC (PVC) than most traditional materials, some of the procedures attain special importance.

To avoid possible damage or deformation of the pipe, its support by the ground in which it is laid should be made as uniform as possible and materials in contact with the pipe must be free from large stones, sharp edged flints or other hard objects. The trench bottom should be carefully examined for irregularities and any hard projections removed. In good uniform conditions, where the trench bottom can be readily brought to an even finish so as to support the pipes uniformly over their length no under-bedding will be necessary. Elsewhere and especially in rock or variable soils containing large stones, boulders, flints, tree roots or soft pockets a prepared bed is necessary. This bed should consist of suitable well compacted selected granular material.

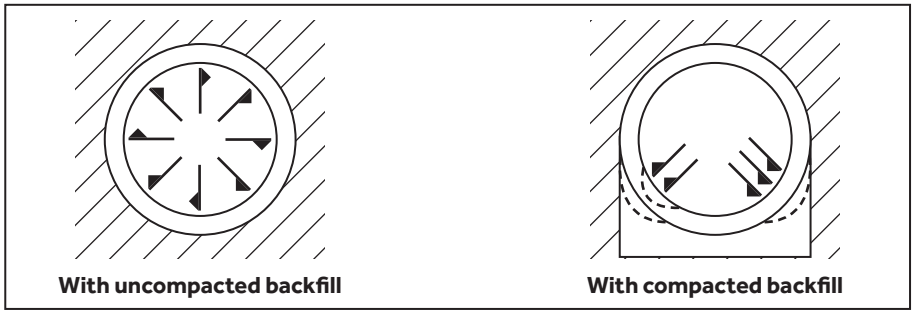
The ideal material for the trench bed and for compacting is one that will pass through a tin sieve but which is free from very fine particles which may impede drainage. The thickness of bed should be a minimum of 150 mm.

In all cases, care should be taken to remove any levelling pegs or temporary packing such as wooden wedges, bricks or stones. Selected granular materials similar to the material used for bedding should then be carefully placed and compacted in uniform layers alongside and under the pipe up to a height of 150 mm or more above the crown. Any trench sheeting if used should be partially withdrawn so as to ensure that the spaces between the pipes and soil faces of the trench are completely filled with well compacted granular materials in order to provide the necessary side support for the pipes and prevent excessive deformation under load. It may be helpful especially when thin wall piping is being laid if the pipe can be full of water during this operation.

Under roads or verges or where mechanical plant is to be used for the placing and or compacting of the backfill the remainder of the first 300 mm depth of fill above the crown of the pipe should be compacted by hand and should consist of selected uniform, readily compactable material, placed and compacted in uniform layers. The remaining fill should then be placed in layers of 300 mm or more depending on the compactors used.

If piping is laid in hot weather, precautions should be taken to allow for the contraction of the line which will occur when it cools to its normal working temperature. The best method is to allow the pipe to fill with cold water from its normal supply when the trench has only been partially backfilled. This will result in the reduction of the overall length of the pipe due to shrinkage and it will therefore be necessary, before final back filling to carefully examine any detachable or other joints to see that sufficient reserve of draw is still available and that they have not become subject to any undue stress.

The ideal material should be free from large clay lumps (retained on a 3 in. sieve) from stones (retained on a 1 in. sieve) and sharp edged stones or flints, vegetable matter and from soil.

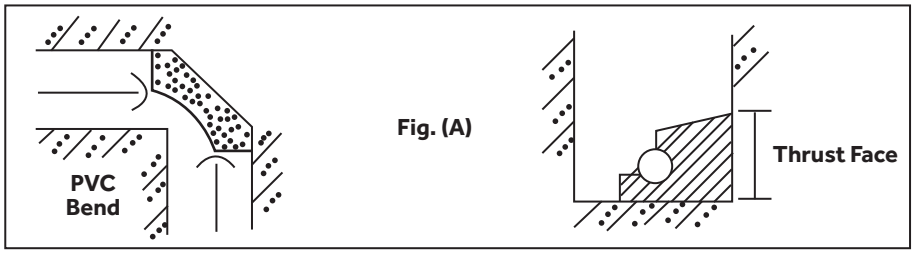


ABOVE GROUND INSTALLATION

The jointing procedure for above-ground pipelines is identical to that for underground pipe lines. Above -ground installations should be fully supported, firmly enough to avoid strain on all joints but flexible enough to allow for a certain amount of thermal expansion in a pipeline. All flanged joints should be supported on both sides. Rubber ring joints should be anchored against end trust. Pipelines should be protected from abrasion by metal supports with felt or foam rubber strips.

THRUST FORCES

When a pipeline is constructed using push-fit joints, joint separation due to internal pressure and resulting thrust forces must be prevented. This is achieved using concrete trust blocks at directional changes, branches, end caps, valves, etc. The design of uPVC pipes provided a safety



factor of 2.0 - 2.5 after a life of 50 years at maximum working pressure. In designing thrust blocks it is logical to apply a similar factor of safety after calculating thrust forces on the maximum foreseeable line pressure.

In view of the flexible nature of uPVC it is desirable to thrust block to install a design to permit the largest possible area of contact between the fitting concerned and the concrete block so that a restraint against excessive flexing as well as thrust, is provided (Fig. A). This feature, in certain soil conditions may also be applied to solvent welded pipelines which need no support against thrust but which can benefit by flexing restraint at abrupt directional changes.

Thrust block should not be allowed to encase the fitting as the external diameter of a uPVC pipe must be left free to distend due to pressure fluctuation. The block may be designed as shown in (Fig. A) or if total encasement is preferred the fitting should first be wrapped in several layers of heavy gauge polythene film prior to concreting to provide freedom of movement and a barrier against abrasion.

This work should be carried out in accordance with the following conditions:

B. Piping Along Bridge

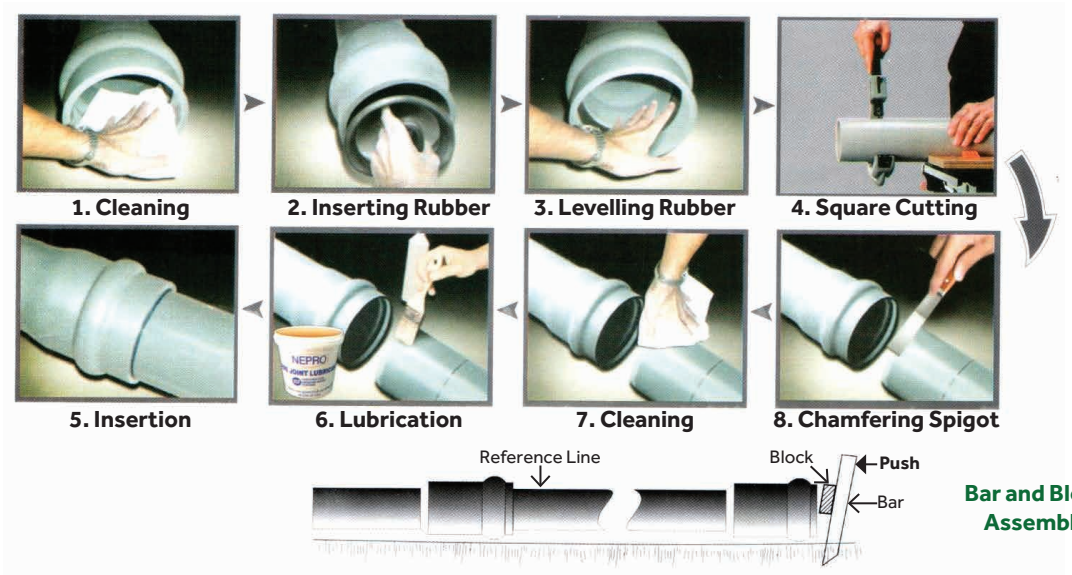
1. When the bridge itself is of curving construction expansion or flexible fitting such as RR joint and dresser joint. The dresser joint should be used.
2. Air valve should be fixed.
3. At the both ends of pipe, concrete protection should be given to protect disconnection of fitting.
4. Metal hanger of pipe may or may not be required depending on the structure of bridge. However, in any case, the pipe should be fixed firm to the bridge not to sway or shake.

C. Pipe Under Railway

1. Such works should be started after due understanding with railway companies or authorities.
2. Piping work should be carried without any interruption against railway operation.
3. At night work, alarming yellow lamp should be provided for traffic safety purpose.
4. Proper protection work or device such as protective concrete or metal casing should be given to pipe to avoid shaking.

XII. Installation Methods

RUBBER RING JOINTING



The following information are intended to assist Engineers and Contractors to take full advantages of the physical and mechanical properties of uPVC pipes and to achieve the desired results.

A) METHOD FOR RUBBER RING JOINT INSTALLATION

1. Ensure that the mating areas of spigot and socket are thoroughly clean.
2. Setting the rubber ring in grove.
3. Assess the full socket depth by simple measurement and mark spigot accordingly
4. Apply lubricant to the spigot side and to the inside of the joint on rubber
5. Accurate axial alignment of the spigot and socket prior to jointing is important, hand feed spigot into rubber joint until resistance from the inner sealing section is felt.
6. Bar and block assembly is recommended because a worker is able to feel the amount of force being used and whether the joint goes together smoothly.
7. If undue resistance to pipe insertion is encountered, disassemble the joint and check the position of the rubber ring

IMPORTANT NOTICE

If pipes are cut on site, make sure that the new spigot ends are cut square with a find toothed saw and are chamfered to half pipe thickness with a coarse file before jointing. For 100 joints use the following amounts of lubricant;

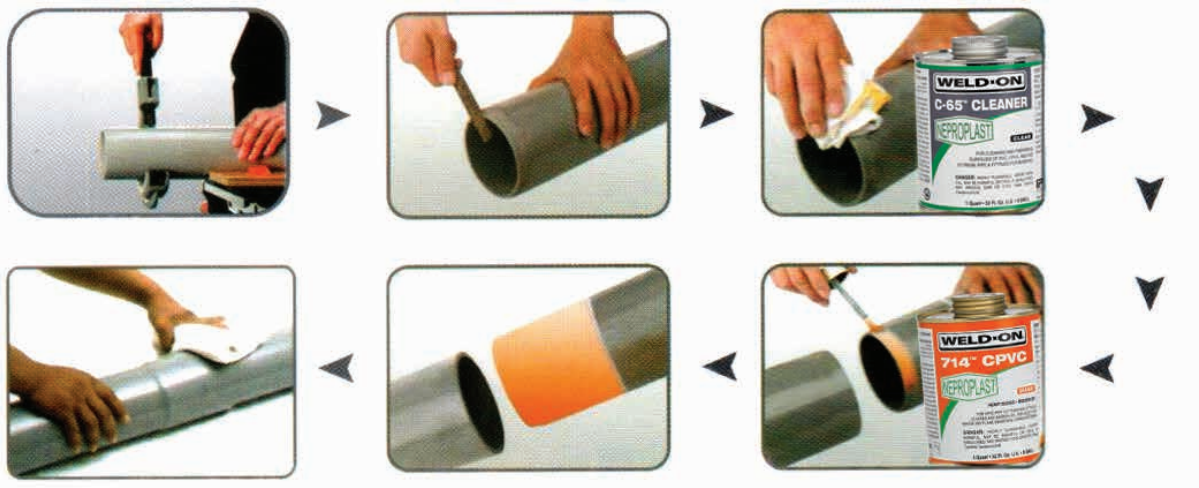
Pipe Outside Diameter DN	Dia. /mm	Kg. of Lubricant
DN 50	63	0,5
DN 80	90	0,85
DN 100	110	1,10
DN 125	125 / 140	1,35
DN 150	160	1,80
DN 200	200 / 225	2,40
DN 250	280	3,15
DN 300	315	3,85
DN 400	400	5
DN 450	450	6
DN 500	500	7

B) METHOD OF SOLVENT WELDED JOINT INSTALLATION

1. Joint Preparation - Cut pipe square with axis, using a fine tooth saw with a miter box or guide. Remove all burrs and break the sharp lead edges.
2. Cleaning & Priming-Surface to be joined must be cleaned and free of dirt, moisture, oil and other foreign material.

APPLYING WELD-ON PRIMER

3. Mark on spigot the full length of the socket side to make sure that the spigot will fit exactly the socket length.
4. Application of solvent cement - PVC solvent cement is fast drying and should applied as quickly as possible, consistently with good workmanship. Follow up the manufacturer's recommendation to both spigot and socket side with an adequate quantity of cement.
5. Joint Assembly - While both the inside socket surface and the outside surface of the spigot of the pipe are wet with solvent cement, forcefully bottom the spigot in the socket. Turn the pipe or fittings 1/4 turn during assembly (but not after the pipe is bottomed) to distribute the cement evenly. Hold for a while until handling strength is developed. Assembly should be completed within 30 seconds after the last application of solvent cement.
6. After assembly wipe excess cement from the pipe at the end of the socket. Gaps in the cement bead around the pipe perimeter may indicate a defective assembly. Handle the newly assembled joints carefully after 1 hour.



IMPORTANCE POINTS OF PIPE INSTALLATION WITH SOLVENT CEMENT JOINTS

1. The jointing surfaces must be clean and dry
2. Sufficient cement must applied to fill the gap between male and female ends
3. The Assembly must be made while the surfaces are still wet and fuild
4. Completed joints should not be disturbed until they have cured sufficiently to withstand handling.
5. Keep the solvent cement closed and shaded when not actually in use. Discard the solvent cement when a noticeable change in viscosity occurs, when the cement does not flow freely from the brush or when the cement appears lumpy and stringy.

Although NEPRO cement joints achieve initial setting in a very short time the joints does not reach its full strength for about 24 hours. Therefore, cemented joints must be left overnight before pressure testing is carried out.

For 100 Joints u se the following amounts of adhesive and primer (Table No. 13)

Pipe Outside Diameter DN	O.D. Dia / mm	Primer (kg)	Adhesive (kg)
25	32	Approx. 0.5	Approx. 0.8
32	40	Approx. 0.7	Approx. 1.1
40	50	Approx. 0.9	Approx. 1.6
50	63	Approx. 1.7	Approx. 1.7
60	75	Approx. 1.3	Approx. 2.2
80	90	Approx. 1.4	Approx. 4.0
100	110	Approx. 1.7	Approx. 8.0
125	125 / 140	Approx. 2.1	Approx. 13.0

Pipe Outside Diameter DN	O.D. Dia / mm	Primer (kg)	Adhesive (kg)
150	160	Approx. 2.5	Approx. 19.0
200	200 / 225	Approx. 4.5	Approx. 26.0
250	280	Approx. 6.5	Approx. 38.0
300	315	Approx. 10.2	Approx. 52.0
400	400	Approx. 12.9	Approx. 62.0
450	450	Approx. 14.4	Approx. 69.75
500	500	Approx. 16.0	Approx. 77.50

XIII. Hydrostatic Testing

The length of test section will be determined by practical reasons such as availability of water or the number of pipes, fittings and joints to be tested. Long pipelines should be tested in sections as main laying progresses.

The pipe length to be tested may be blanked off using a blank iron or steel flange previously drilled and tapped for test equipment connection and strutted as necessary against end thrust. The blank flange may be attached to the pipeline by a Viking Johnson Flange Adapter or similar.

Testing should be preferably not be carried out against closed valves. All charging and testing should preferably be carried out from the lowest point of the under test section and all testing equipment should be located at this point. The pressure gauge also should be located at the lowest point or adjustment must be made for the level of the pressure gauge relative to the pipe's position.

Prior to testing, care should be taken to ensure that all anchor blocks have attained adequate maturity and that any solvent welded joints included in the pipe system have developed full strength. Correct support and anchorage of any above ground section of the pipeline is also necessary. Underground pipelines should be back-filled, taking particular care to consolidate around lengths which may have been deflected to negotiate curves. All joints may be left exposed until testing is completed.

With the stand pipe, valves and pressure gauge assembled, filling of the main can begin. The main should be charged slowly, preferably from the lowest point with any air cock in the open position. They should be closed in sequence from the lowest point when water, visibly free from aeration, is being discharged through them.

Satisfactorily charged, the main should be allowed to stand overnight to allow any residual air to 'settle-out' and percolate to the pipe soffit. Re-venting is then necessary and any water deficiency should be made-up.

Pressure testing can then begin by pumping slowly until the required test pressure is attained. A single or double cylinder hand pump should be used for this purpose. Mechanical pumps are not recommended unless incorporating a pre-set blow-off mechanism.

The hydrostatic test specification will be at the discretion of the responsible Engineer but should not exceed 1 1/2 times the designed working pressure of the lowest rated component in the system and a time duration of 24 hours.

A permissible water loss of 3 litres per kilometre of pipe per 25 mm nominal bore, per 3 bar of test pressure, per 24 hours, may be considered reasonable.

Air testing is not recommended if, however, for practical reasons, pneumatic testing is necessary, this should be limited to a maximum pressure of 1.5 bar.

Air leakage can be detected by applying soap solution to the joints or by pre-odourising the air with Ethyl Mercaptan. This will reduce the time duration of an otherwise long term pneumatic test.

During any air-pumping operations no one should be working on, or near, the test section and precautions should be taken to avoid heavy objects striking the main whilst under pneumatic pressure.

XIV. Flow & Friction

Friction Losses

The smooth bores of uPVC pipes have better flow characteristics than those of metal pipes. The following is the co-efficient of friction given when using the Hazen-Williams formula:

$$f = 0.2083 \left(\frac{100}{C}\right)^{1.85} \frac{Q^{1.85}}{di^{4.87}}$$

Q = Flow in gallons/min
di = Inside dia of pipe in inches
C = Constant for inside roughness of pipe
f = Friction head in feet of water / 100 feet of pipe

Values of C
up to 315 mm C = 137 - 150
over 315 mm C = 151

Head losses attributable to fittings can be found by applying

$h = \frac{KV^2}{2g}$

h = Head loss (m).
K = Constant
V = Velocity of fluid (m/s)
g = Acceleration due to gravity (m/s^2)

Values of K

Elbow 90° - 1.00
Elbow 45° - 0.40
Moulded Bends 90°C - 0.75
Formed Bends 90° - 0.20
Formed Bends 22 1/2° - 0.10
Flow in Line - 0.35
Flow in line to branch or branch to line - 1.20

Surge Pressures

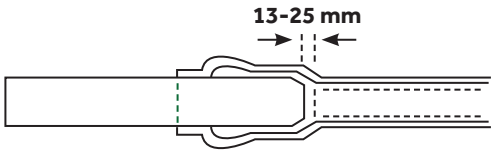
Surge pressures commonly termed as "Water Hammer" are generated in any piping system when a flow changes its velocity.

$$P = \frac{4660\,V}{2.3\,g\sqrt{\frac{1+K\,(DR-2)}{E}}}$$

P = Surge pressure in PSI
V = Maximum velocity change in Ft/Sec.
g = Acceleration due to gravity 32.2
K = Friction head in feet of water / 100 feet of pipe
DR = Pipe outside diameter / wall thickness
E = Modulus of elasticity of the pipe in PSI. (420,000 PSI for PVC)

Expansion Gap

To be sure that the spigot enters the socket to within 13 -23 mm of the bottom of the socket dimension, the depth of chamber should be one third of the wall thickness of the pipe.



Calculation of pipe diameter based on required flow an velocity

$$ID = 10\sqrt{\frac{40\,.\,Q}{.\,V}}$$

ID = Inside diameter (mm)
Q = Flow rate in L/S orm / F
V = Velocity of Flow (M/S)

*** Determination of the length changes caused by difference in temperature**

ΔL = L ΔT L
ΔL = IN°C, ΔL = MM
L for uPVC = 0.05

XV. Thermal Movement

Where the temperature of a uPVC pipeline is likely to vary due to atmospheric temperature, it is important to plan the variations in pipeline length which may arise as a result of temperature differences. Expansion and contraction can be calculated using the formula.

dl = ∞ x L x dt where, dl = Change in length in millimeters
∞ = 0.08 mm / m / C
L = Original length of pipe in meters
dt = Total temperature range in 0°C

Calculation of expansion and contraction should take account of the minimum and maximum foreseeable temperature conditions. When the total length variation of the pipeline has been established, the positioning of both support and anchor brackets can be determined.

Anchor brackets can be so arranged to sub-divide the total length variation and to control movement in a specific direction. Support brackets must allow the pipeline to move freely. It is normally possible by correct bracket arrangement to direct movement in such a manner that this is accommodated by directional changes in the line. Expansion bellows may be used to accommodate excessive movement but in such instances the pipes so connected must be restrained against possible separation.

Any line valves must be firmly anchored and independently supported so that no stresses are transmitted to the pipelines.

PIPE BRACKETS

Standard or purpose made metal pipe brackets are normally employed. These should be of the maximum possible bearing width and should have no sharp edges likely to cause pipe damage.

The brackets may be plastic coated but where this is not practical a layer of rubber felt or similar soft, non abrasive membrane must be fixed to the bearing face prior to installation.

PIPE SUPPORTS

UPVC pipes must be adequately supported. The following table shows the recommended support intervals for horizontal pipes conveying water. Where liquids of greater density are being conveyed the intervals of support should be reduced proportionately.

For vertical pipe runs, the support intervals may be increased to double those shown except in exposed situations where wind loading etc. may dictate adherence to the intervals tabulated below.

Nom. Size	Classes II & III		Classes IV & V	
	20°C	40°C	20°C	20°C
	m	m	m	m
12	-	-	0.70	0.60
20	-	-	0.77	0.70
25	-	-	0.85	0.80
32	-	-	0.90	0.85
40	-	-	1.07	0.90
50	1.07	0.92	1.15	1.00
63	1.22	1.07	1.30	1.15
75	1.30	1.15	1.37	1.22
90	1.34	1.18	1.45	1.26
110	1.37	1.22	1.52	1.30
140	1.52	1.37	1.67	1.45
160	1.60	1.45	1.82	1.60
180	1.75	1.52	2.00	1.75
200	1.82	1.60	2.05	1.82
205	1.90	1.67	2.20	1.90
250	2.05	1.75	2.37	2.05
315	2.30	2.05	2.52	2.20
355	2.37	2.20	2.67	2.42
400	2.60	2.45	2.75	2.60
450	2.90	2.75	2.97	2.82
500	3.20	3.05	-	-

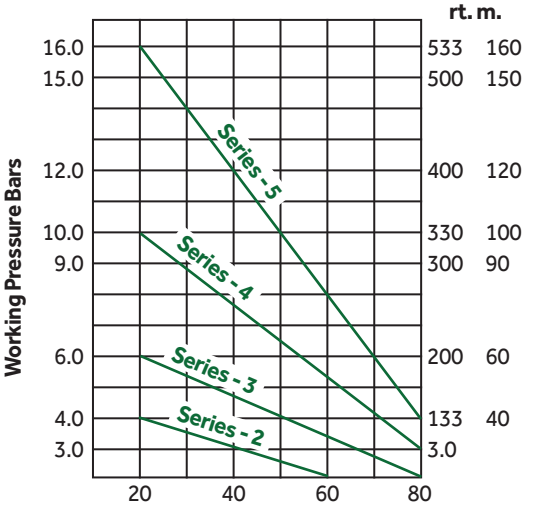
XVI. uPVC Pipe at Elevated Temperature

When uPVC pressure pipe operates at temperature other than the temperature at which the pipe is rated (20 or 23°C) pressure rating should be established on thermal design factors. Examples given below are for guidance only.

(Fig. 1)

Pressure Temp. Relationship Ambient Variable Internal Temp. 20°C

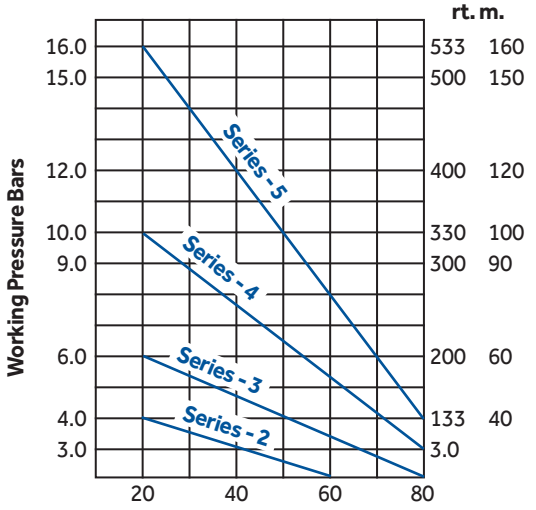
Ambient Temperature of 40°C a required working pressure of 6.0 bars use a 10 bar rated pipe



(Fig. 2)

Pressure Temp. Relationship Internal Variable Internal Temp. 20°C

Ambient Temperature of 40°C a required working pressure of 6.0 bars use a 10 bar rated pipe



Temperature Conversion

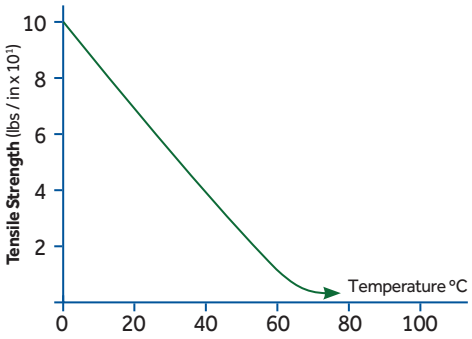
F = 9/5(C+32) **C = (F-32)5/9**

Pressure Temperature Relationship

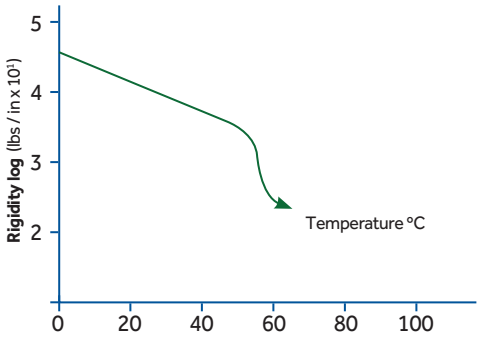
Temperature		Temperature Correction Factors
°C	°F	
21	70	1.00
27	80	0.90
32	90	0.75
38	100	0.62
43	110	0.50
46	115	0.45
49	120	0.40
52	125	0.35
60	140	0.22

Where the liquid carried in a pipeline is 20°C and the ambient temperature is higher than 20°C - the maximum working pressure should be reduced by 1 1/2 % per degree above 20°C.

Where liquid carried in a pipeline is 20°C and the ambient temperature is 20°C - the maximum working pressure should be reduced by 2% for every degree °C the fluid temperature is above 20°C. The aforementioned pressure reductions apply to maximum operating temperature of 60°C.



Relationship between Tensile Strength & Temperature



Relationship between Rigidity & Temperature
